FixServices

UX User Flow for Model Training

A practical explanation of how customers, service providers, and administrators move through the local home-service booking platform.

1. Purpose of the User Flow

A user flow describes the steps a person takes in an application, the decisions they make, and the response the system should provide. In FixServices, the main customer goal is to find a suitable local service, review its details, and submit a booking. The provider goal is to list services and respond to bookings. The administrator helps maintain trustworthy provider and service listings.

2. Main Customer Journey

1. Open FixServices

The customer lands on the homepage and understands that the platform connects customers with local service providers.

2. Choose a location

The customer selects a district, then a taluka, then a town or village. The interface should make the order clear and avoid requiring a PIN code.

3. Choose a service category

The customer selects a category such as plumbing, electrical work, cleaning, painting, or appliance repair.

4. View matching services

The system filters active listings by the selected category and the provider's saved location. It displays matching service cards.

5. Review a service

The customer checks the provider name, service description, price, location, and rating information when available.

6. Book the service

If required, the customer signs in or registers, enters booking details and the service address, and submits the request.

7. Track the booking

The customer checks the booking status, such as pending, accepted, completed, or cancelled, depending on the implemented workflow.

3. Local Service Discovery Example

Example: a customer wants an electrician in Karveer taluka, Kolhapur district, Maharashtra.

Step 1 — Location: The customer chooses Maharashtra, Kolhapur, Karveer, and the appropriate town or village.

Step 2 — Category: The customer chooses Electrical Services.

Step 3 — Filtering: The application searches for active electrical-service listings associated with approved providers whose stored location matches the selected area.

Step 4 — Results: The website shows matching service cards with available descriptions, prices, provider details, and ratings.

Step 5 — No results: If no listing matches, the interface explains this clearly and lets the customer change the location or category.

Important distinction: Matching district, taluka, and town/village names is location-based filtering. It does not calculate the physically nearest provider. True distance-based sorting would require geographic coordinates and a distance calculation.

4. User Flows by Role

A. Customer

• Visits the homepage.

• Selects district, taluka, town or village.

• Chooses a service category and reviews matching services.

• Opens a service to inspect provider details and price.

• Logs in or registers if booking requires an account.

• Submits a booking and receives a confirmation message.

• Tracks booking status and, if the feature exists, leaves a review after completion.

B. Service provider

• Registers as a provider and enters profile and location details.

• Waits for administrator approval if approval is required.

• Adds service listings, descriptions, and prices.

• Receives customer booking requests.

• Accepts or rejects requests if those actions are supported.

• Updates the booking status as work progresses, if supported.

C. Administrator

• Signs in to the administration area.

• Reviews provider registration requests.

• Approves or rejects providers.

• Manages service categories and listings.

• Monitors users, bookings, or reported issues where these features exist.

5. User Actions and Expected System Responses

User action	Expected system response
Selects a location	Shows or enables the relevant district, taluka, and town/village choices.
Selects a category	Filters services for the selected category and area.
No provider matches	Displays a helpful empty-results message and offers a way to change filters.
Opens a service	Shows available service and provider details.
Tries to book while logged out	Requests login or registration if authentication is required.
Submits a valid booking	Saves the request and displays a confirmation.
Provider responds	Updates the booking status so the customer can see the latest state.
Provider is not approved	Keeps that provider's services out of public search results.

6. Training Examples for a UX Model

When preparing examples to train or evaluate a model that explains user interactions, each example should identify the user's intent, their action, the expected application behavior, the resulting UI state, and a plausible next step.

Training field	Example
User intent	Find an electrician in the user's town.
User input/action	Selects Kolhapur district, Karveer taluka, a town/village, and Electrical Services.
Expected system behavior	Returns active electrical-service listings from approved providers matching the selected area.
Expected UI state	Shows matching service cards or a clear no-results message.
Likely next action	Opens a service card or changes the location/category.

7. Useful Scenarios for Training and Testing

• A first-time customer chooses an area and finds a service.

• A search returns no providers for the selected area and category.

• A customer attempts to book without signing in.

• A provider registers and remains pending approval.

• An approved provider adds a service listing.

• A customer submits a booking and checks its status.

• A provider accepts, rejects, or completes a booking where the application supports those actions.

• A customer changes the town or category after receiving no results.

8. UX Design Principles

Clear location hierarchy: Guide the customer from district to taluka to town/village.

Minimal effort: Avoid unnecessary fields and do not require a PIN code if the platform is designed around local area names.

Visible feedback: Confirm searches, bookings, and status changes.

Helpful empty states: Explain why results may be missing and offer a recovery action.

Trust and transparency: Show provider details and only publish providers that meet the application's approval rules.

Accessibility: Use readable labels, keyboard-friendly controls, and clear error messages.

9. Keep Model Training Grounded in the Real Application

The expected behavior used in training data should match the actual FixServices implementation. If automatic GPS distance calculation, live notifications, online payment, or customer reviews are not implemented, describe them as future possibilities rather than existing capabilities. The model should not promise an action or feature that the application cannot perform.
